

Retail & Wholesale Pricing — Full Flow

Smart Accounting · Inventory, branch/location overrides, and sales (invoices, cash sales, POS). Document generated for operational reference.

Summary. Each inventory item has a default *retail* unit price (`unit_price`). Optional *wholesale* pricing is enabled per item; resolved prices can differ by **location** and **branch**. At sale time the user picks **retail** or **wholesale** when the item supports both; the choice is stored on each line as `price_tier` .

1. Setup on the inventory item

1. Open **Inventory** → **Items** (create or edit).
2. Enter the default **retail** price (this remains the primary “shelf” price).
3. If the product has a wholesale channel, turn on wholesale and set **wholesale unit price** (default for the item).
4. Optional: set **branch** or **location** price rows — both retail and wholesale columns apply where configured; resolution is *location* → *branch* → *item default*.

Example A — Single default prices (no overrides)

Field	Value
Item	Rice 25kg (code RICE-25)
Wholesale enabled	Yes
Retail <code>unit_price</code>	45,000 TZS
Wholesale <code>wholesale_unit_price</code>	41,000 TZS

Any sale line for this item can use either tier; the system suggests the price for the tier you pick.

Example B — Location overrides retail and wholesale

Scope	Retail	Wholesale
Item default	10,000	9,200
Branch “Dar”	10,200	9,350
Location “Dar Storefront”	10,500	9,500

If the user’s session location is “Dar Storefront”, both tiers resolve to the location row when present; otherwise branch, then item.

2. Behaviour in the item picker (modal)

- If **wholesale is off** for the item: only retail pricing applies; no “price type” row is shown.
- If **wholesale is on**: modal shows **Price type** with *Retail* (default) and *Wholesale*; unit price updates when the tier changes.
- Foreign currency: base prices are in functional currency (e.g. TZS); the modal converts using the sale currency and exchange rate.

Example C — Modal choice (functional currency)

User action	Resulting line
Select RICE-25, tier <i>Retail</i> , qty 2	<code>unit_price</code> 45,000 · <code>price_tier</code> retail
Same item, tier <i>Wholesale</i> , qty 10	<code>unit_price</code> 41,000 · <code>price_tier</code> wholesale

3. Sales surfaces (same rules)

Surface	What happens
Sales invoices (create / edit)	Line modal + hidden <code>price_tier</code> ; duplicate lines merge by <code>inventory_item_id</code> + tier where implemented.
Cash sales (create / edit)	Same modal pattern; rows carry <code>data-line-key = id_tier</code> ; adding the same item again with the same tier merges quantity and re-validates stock.
POS	Item modal includes tier; cart stores <code>price_tier</code> per line; checkout sends tiers to the server.

4. Server-side validation (conceptual)

- `items.*.price_tier` is optional; allowed values: `retail` , `wholesale` .
- If an item does not have wholesale enabled, choosing wholesale should fail validation (tier must match item capabilities).
- Line items are consolidated or keyed so the same physical item at different tiers can appear as separate lines (e.g. 5 retail + 10 wholesale).

5. End-to-end diagram (conceptual)

6. Quick reference — fields

Layer	Retail	Wholesale
Item	<code>unit_price</code> , <code>has_wholesale</code>	<code>wholesale_unit_price</code>
Branch / location price rows	<code>unit_price</code> (override)	<code>wholesale_unit_price</code> (override)
Sale line	<code>unit_price</code> (amount charged) + <code>price_tier</code> (<code>retail</code> <code>wholesale</code>)
